1. Introduction

This document is for the team or personnel who are responsible for the technical support of YB Currency Converter application—supporting users, troubleshooting problems, and extending or adjusting the functionality as required.

1.2 Functional overview

The application is a CLI application to run on a Windows or Mac computer where Python is readily installed. The user will start the application as instructed in the User Documentation. For detailed functional information, refer to User Documentation.

2. Overall Architecture

The following diagram shows the overall architecture of the application, YB Currency Converter.

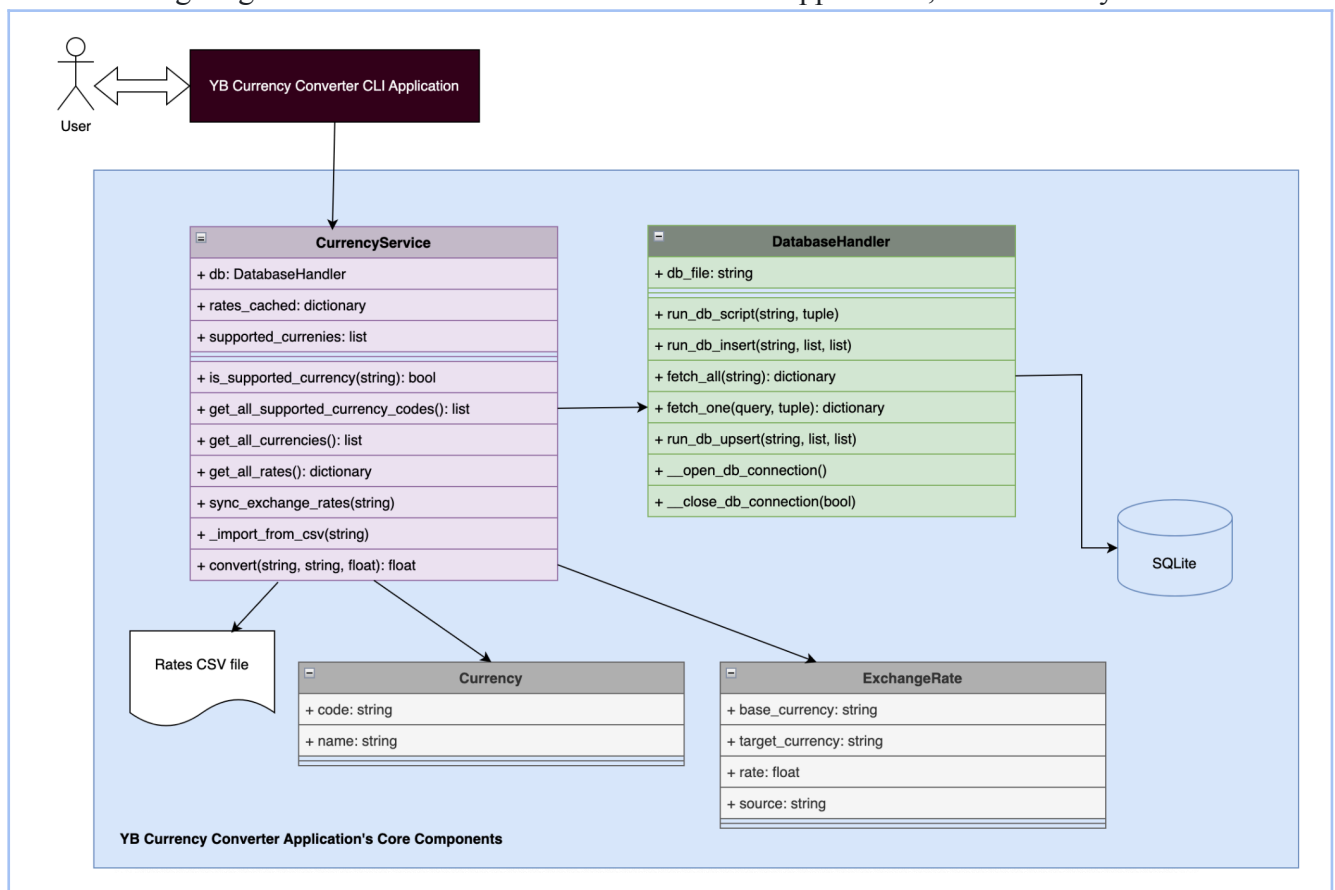

Figure 1. Overall architecture of YB Currency Converter

The system is provided as a command-line interface (CLI) application which has the components supporting to perform the necessary currency conversion. As it is drawn in the illustration above, the application is used by the user as a CLI application. The CLI has the components supporting its full functionality. **CurrencyService** is a service class which takes care of dealing with the database to load

the exchange rate information from an external CSV file and save them in the database overwriting the default setup from the application. Then all the required information is loaded to have the application ready for the currency conversion.

DatabaseHandler is a class which takes care of database related activity. Two data model classes—Currency and ExchangeRate—are used for cleaner access and operation with the database.

The application utilizes the sqlite3 module, which is included in the Python standard library (**Lutz, 2009**), to manage persistent data storage.

3. Database

SQLite is used for YB Currency Converter and the following tables are used to keep the data.

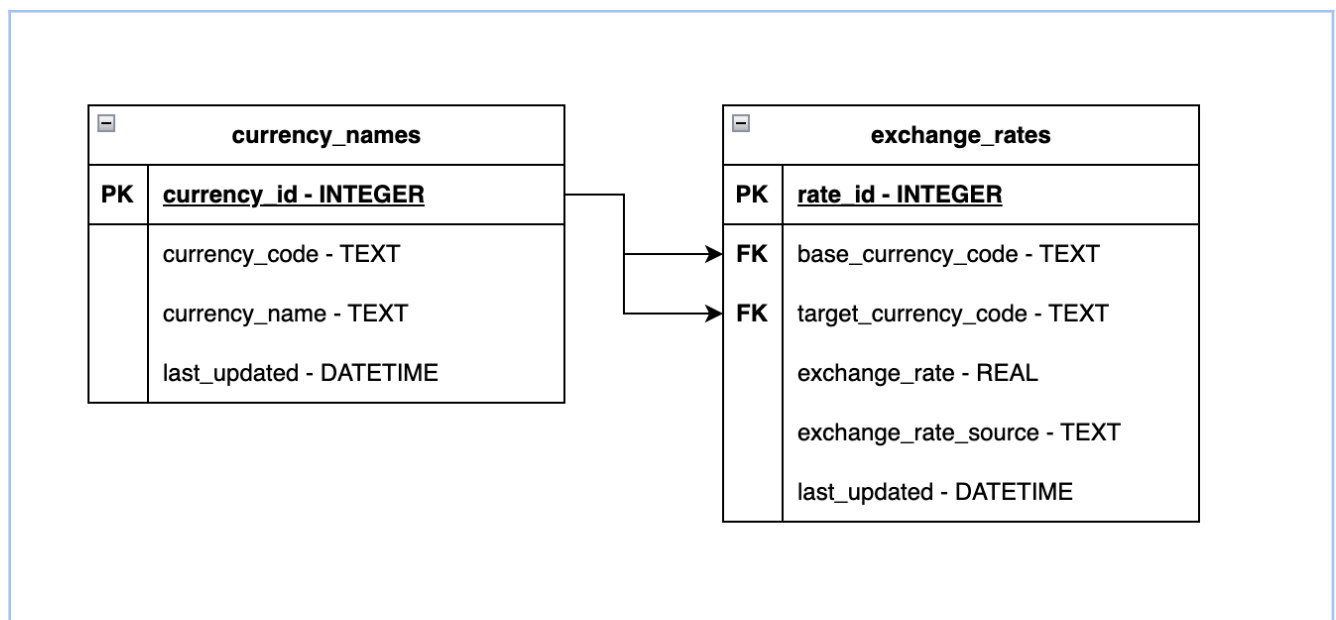

Figure 2. Two tables and their relation

In the exchange_rates table, base_currency_code column and target_currency_code column make a composite unique key.
